Supplement of

Exploring 2016–2017 surface ozone pollution over China: source contributions and meteorological influences

Figure S1. Spatial distribution of bimonthly mean (a) anthropogenic NO emissions, (b) anthropogenic CO emissions, (c) anthropogenic NMVOC emissions averaged for 2016–2017.
Figure S2. Simulated vs. observed daily maximum 8 h average (MDA8) ozone concentrations at the ensemble of the 169 cities categorized by the 9 city clusters for March-October 2016-2017. The colors denote different months. The mean concentrations, standard deviations, correlation coefficients (r), the 1:1 line, and number of cities in each city cluster are shown inset.
Figure. S3 Time series of observed and simulated daily MDA8 ozone concentrations from the nested model (red) and the global model (blue) at 15 representative cities from the nine city clusters in March-October 2017. The mean concentrations and correlation coefficients (r) are shown inset.
Figure S4. Spatial distribution of bimonthly mean (a) daily maximum 2-meter air temperature with 850hPa horizontal wind overlaid, (b) specific humidity, (c) cloud cover fraction, and (d) 500hPa vertical velocity averaged for 2016–2017.
Figure S5 Spatial distribution of bimonthly mean (a) soil NO emissions, (b) column integrated NO emissions, (c) biogenic isoprene emissions averaged for 2016–2017, and (d) biomass burning CO emission in 2014 used in the model.
Figure S6. Zonal-vertical distribution of (a) lightning NO emissions and (b) lightning ozone enhancement at 30°N.
Figure S7. Spatial distribution of bimonthly mean H$_2$O$_2$/HNO$_3$ concentration ratios (an indicator of ozone chemical production regime) at the surface averaged for 2016–2017. Areas with H$_2$O$_2$/HNO$_3$ values lower than 0.3 can be considered as the VOC-limited regime, while values higher than 0.6 can be considered as NO$_x$-limited.
Figure S8. Differences in May-August mean domestic anthropogenic PM$_{2.5}$ contribution between 2017 and 2016 in unit of [$\mu$g m$^{-3}$].
Figure S9. Spatial distributions of Chinese domestic anthropogenic contributions to surface MDA8 ozone in 2017 estimated from (a) zero-out methods (difference between the BASE simulation and the noCH simulation), (b) 20% perturbation method (five times of difference between the BASE simulation and the CH20off simulation). (c) shows the difference between (a) and (b).
Figure S10. Differences in May-August mean daily maximum 2-m air temperature between 2016-2017 period and 2013-2015 period.
