15 **Figures**

16 **Figure S1** Mathematical parameters for PMF results of Ranges 1, 2, 3 and Range Combined. Left panels (a-
17 d) shows Q/Qexp values as a function of the number of factors, and right panels (e-h) show mean scaled
18 residuals. From top to bottom, the results for Range 1 (a, e), Range 2 (b, f), Range 3 (c, g) and Range
19 Combined (d, h) are shown.

20 **Figure S2** The contamination factor resolved from 6-factor result in Range 2, with the main masses 324 Th
21 and 339 Th showing apparent negative mass defect

22 **Figure S3** Time series of three contamination compounds in 1-min time resolution

23 **Figure S4** Normalized signals for three fluorinated compounds during a 3-h cycle (180 minutes), with
24 $(\text{CF}_2)_3\text{CO}_2\text{HF}\cdot\text{NO}_3^-$ (275.9748 Th) in red, $(\text{CF}_2)_5\text{C}_2\text{O}_4\text{H}^-$ (338.9721 Th) in blue, and $(\text{CF}_2)_6\text{CO}_2\text{HF}\cdot\text{NO}_3^-$
25 (425.9653 Th) in black. We selected 25 cycles and normalized all the cycles by their individual maximum.
26 The yellow window shows the zeroing time, for around 10 minutes, which has been removed from the data
27 analysis. Light colors display the individual cycles, and the bold solid colors stand for the average for each
28 compounds.

29 **Figure S5** Time series correlation between three contamination compounds, in 1-min time resolution (upper
30 panels: a, b), and 1-h time resolution (lower panels: c, d), with zero data (left: a, c) and without zero data (right:
31 b, d).

78 Fluorinated compounds / Contamination factor

79 During the campaign, an automated instrument zeroing every three hours was conducted, by switching a valve
80 to pass the air through a HEPA filter. Each zeroing process lasted for 10 min. While the zeroing successfully
81 removed the low-volatile HOM and H₂SO₄, the zeroing process introduced contaminants into the inlet lines.
82 The contaminants were primarily different types of perfluorinated organic acids, often off-gassing from e.g.
83 Teflon tubing. For IVOC contaminants, these would be flushed through the inlet, while (E)LVOC would
84 condense onto the inlet walls and not come off. However, SVOC contaminants may stick to the inlet tubing
85 and slowly evaporate back into the sampled air. We removed all the 10-min zeroing periods, and averaged the
86 data to 1-h time resolution, but contaminants were still identified in all ranges by binPMF.

87 Contamination contributed 10%, 3%, 19% and 4% to Range 1, 2, 3, and Combined, respectively, in the binPMF
88 solutions where the contamination factor was first separated. This also explains why the contamination factor
89 was separated much earlier in Ranges 1 and 3 than in Range 2. However, despite contributing slightly more to
90 Range Combined than to Range 2, the contamination factor was separated when the factor number was
91 increased by one in Range Combined. Here, the difference in volatility of the contaminants in the different
92 sub-ranges may play a role, such that the contaminants in different sub-ranges behave differently. Thus, the
93 behavior of the contamination factor across the combined range is not consistent. Therefore, we examined the
94 zeroing effect with finer time resolution, i.e. 1 min, with three of the largest fluorinated compounds in each
95 range of our mass spectrum, (CF₂)₃CO₂HF·NO₃⁻ (275.9748 Th), (CF₂)₅C₂O₄H⁻ (338.9721 Th), and
96 (CF₂)₆CO₂HF·NO₃⁻ (425.9653 Th). Since the overall signal levels were very low for these compounds, the time
97 series became very noisy with such high time resolution. This made it impossible to perform HR fitting for the
98 data, and instead we summed up the signal from the mass ranges where we expected unperturbed signal from
99 these ions.

100 The time series with sawtooth pattern of the three fluorinated compounds is shown in Figure S3 in Supplement.
101 From the time series, we selected a period of around three days of the 3-h cycles (25 in total), and in Figure
102 S4 the cycles were aligned and superimposed on top of one another, normalized by the maximum during the
103 zeroing. The normalized signals of the three compounds are shown in light colors, and the mean values shown
104 in bold solid lines. This data includes also the zeroing periods to highlight the effect, but these periods were
105 removed from the data used for our PMF analyses.

106 The signals of the three fluorinated compounds increased by 10 to 20 times during the zeros, due to off-gassing
107 either in the filter or in the tubing in the zeroing setup. Immediately after the zeroing was stopped, signals of
108 all three compounds dropped by about 60-90%, followed by a gradual decay. The decay period coincided with
109 our ambient sampling, and therefore these signals are part of our dataset. It is evident that the three fluorinated
110 compounds were from the same source (zeroing process), but due to their different volatilities, they were lost
111 at different rates. This, in turn, means that the spectral signature of this source will change as a function of

112 time, at odds with one of the basic assumptions of PMF. Panels a and b in Figure S5 displays the temporal
113 correlation with and without zeroing period with 1 min time resolution. The correlation coefficients dropped
114 greatly when the zero period was removed, from 0.9 to 0.3 for R^2 between 276 Th and 339 Th, and 0.8 to 0.1
115 between 276 Th and 426 Th. Similar effect is also found with the 1 h averaged data (Fig. S5c, d).

116 This detailed analysis of fluorinated contamination in our system was here merely used as an example to show
117 that volatility can impact source profiles over time. In this case, the contamination factor was still identified
118 both from the separate sub-ranges and from the combined data set using binPMF. However, the contamination
119 profile in the combined range is now averaged, compared to that from separate ranges: the fractional
120 contributions of contamination compounds to this profile, vary during the process of each zeroing due to
121 different volatility properties. In Figure S6, contamination factor profiles from Range 3 and Range Combined
122 were compared. It can be clearly seen that the profile of Range Combined is more noisy than that of Range 3,
123 probably due to the varied fractional contributions of contamination compounds to the profile. In ambient data,
124 products from different sources can have undergone atmospheric processing, altering the product distribution.
125 Our aim with this analysis was to highlight the importance of differences in the sink terms due to different
126 volatilities of the products. This may be an important issue for gas phase mass spectrometry analysis,
127 potentially underestimated by many PMF users, as it is likely only a minor issue for aerosol data, for which
128 PMF has been applied much more routinely. If failing to achieve physically meaningful factors using PMF on
129 gas phase mass spectra, our recommendation is to try applying PMF to sub-ranges of the spectrum, where
130 IVOC, SVOC and (E)LVOC could be analyzed separately.
